Abstract

A network structure for canonical coordinate decomposition is presented. The network consists of two single-layer linear subnetworks that together extract the canonical coordinates of two data channels. The connection weights of the networks are trained by a stochastic gradient descent learning algorithm. Each subnetwork features a hierarchical set of lateral connections among its outputs. The lateral connections perform a deflation process that subtracts the contributions of the already extracted coordinates from the input data subspace. This structure allows for adding new nodes for extracting additional canonical coordinates without the need for retraining the previous nodes. The performance of the network is evaluated on a synthesized data set.

Keywords: Canonical coordinates; Singular value decomposition; Deflation; Iterative learning

1. Introduction

Canonical correlation analysis (Hotelling, 1936; Anderson, 1958) provides a minimal description of the correlation between two data channels by concentrating the linear dependence of the channels into a small set of canonical variables. Canonical correlations are maximal invariants to uncoupled linear transformations of two-channel data. The corresponding canonical coordinates resolve the channels into coordinates that are only pairwise correlated. Canonical coordinates have been used to decompose Wiener filters and Gaussian communication channels into their canonical modes where each mode corresponds to a scalar Gaussian channel, or Wiener filter (Scharf & Thomas, 1998; Scharf & Mullis, 2000). They provide an elegant framework for analyzing linear dependence and mutual information between two data channels. In this coordinate system, the linear dependence and mutual information between the original channels are decomposed into those of canonical coordinates of the channels, which are determined by the corresponding canonical correlations. The canonical correlation associated with each pair of canonical coordinates determines the contribution of that pair to the linear dependence and mutual information between the channels (Scharf & Mullis, 2000).

The conventional method of finding canonical coordinates involves computation of square-root-inverses of covariance matrices followed by a singular value decomposition (SVD) of a coherence matrix. These operations become computationally intractable and inefficient especially for large dimensional data. In addition all the singular values and singular vectors of the coherence matrix have to be evaluated even though only the most significant singular values and their associated singular vectors are used in most applications. These deficiencies make the conventional scheme inefficient for real-time applications. Consequently, to perform the canonical coordinate decomposition efficiently, a method is required to extract the most significant canonical coordinate pairs and the corresponding canonical correlations recursively, and without any matrix inversion, matrix square root computation or direct SVD operations.

Neural networks have been proven to be powerful tools for performing linear and nonlinear transformations. Several neural network-based approaches have been reported for extracting principal components of a stochastic vector process directly from the input data set. Oja (1982) proved that a linear model with a single node trained with a normalized Hebbian rule can extract the dominant principal component of a stationary vector process. Sanger (1989) and Foldiak (1989), extended Oja’s work to the multi-node case in order to simultaneously extract the first m principal components of a vector process. Diamantaras and Kung (1994) exploited

the idea of using lateral connections with anti-Hebbian
learning to recursively extract the principal components.
In a different approach, based on recursive least squares
(RLS) learning, Bannour and Azimi-Sadjadi (1995)
proposed another structure for recursive extraction of
principal components. Readers are referred to Diamantaras
and Kung (1996) for a review of other related work in this
area. Kung and Diamantaras (1994) also introduced a
network structure for computing the reduced-rank Wiener
filter. A network-based approach has been reported in Lai
and Fyfe (1999) for performing canonical correlation
analysis. However, this network only finds the most
significant canonical coordinate pair and the correspond-
ing canonical correlation.

In this paper a network and a set of updating rules for
performing canonical coordinate decomposition is pre-
sented. First, the problem of finding the first canonical
coordinate pair is formulated as a constrained minimization
problem. Then, given the first \( r \) canonical coordinate pairs,
the problem of finding the \( (r+1) \)th pair is formulated as one of
finding the first canonical coordinate pair after the
contributions of the first \( r \) pairs are deflated from the input
data subspace. This formulation is used to propose a
network structure that consists of two single-layer linear
subnetworks. The weights of the subnetworks are trained
using a stochastic gradient descent learning algorithm. Each
subnetwork includes a set of lateral connections that whiten
the output. The structure of each subnetwork is similar to
the structure of the single network proposed by Diamantaras
and Kung (1994). The lateral connections are trained to
deflate the contributions of the already extracted canonical
coordinates from the input data subspace. This structure
allows for adding new nodes for extracting a new canonical
coordinate without the need for retraining the previous
nodes. This is very useful since in most cases the number of
canonical coordinates or canonical correlations required is
not known a priori. In these cases a test of linear dependence
or mutual information may be performed to determine
whether additional canonical coordinate pairs need to
be extracted. A simulation example is given to demonstrate
the validity of the proposed network and the corresponding
learning rules.

2. A review on canonical coordinate decomposition

Let us follow the development of Scharf and Mullis
(2000) and consider the two random vectors, \( \mathbf{x} \in \mathbb{R}^{m \times 1} \) and
\( \mathbf{y} \in \mathbb{R}^{m \times 1} \) with \( m \) being the smaller dimension \( (m \leq n) \).
Assume that \( \mathbf{x} \) and \( \mathbf{y} \) have zero means and share the
composite covariance matrix

\[
E \left[ \begin{bmatrix} \mathbf{x}^T \\ \mathbf{y}^T \end{bmatrix} \right] = \begin{bmatrix} R_{xx} & R_{xy} \\ R_{xy} & R_{yy} \end{bmatrix}
\]

This composite covariance matrix has the following block
triangular decomposition

\[
\begin{bmatrix} F^T & 0 \\ 0 & G^T \end{bmatrix} \begin{bmatrix} R_{xx}^{1/2} & 0 \\ 0 & R_{yy}^{1/2} \end{bmatrix} \begin{bmatrix} R_{xx} & R_{xy} \\ R_{xy} & R_{yy} \end{bmatrix} = \begin{bmatrix} I & K \\ K & I \end{bmatrix}
\]

where \( R_{xx}^{1/2} R_{xx}^{1/2} = I, R_{xy}^{1/2} R_{xy}^{1/2} = R_{xy}, \) and \( F, G \) and \( K \)
are chosen to be the SVD of the coherence matrix \( C = R_{xx}^{-1/2} R_{xy} R_{yy}^{-1/2} \).
That is

\[
C = R_{xx}^{-1/2} R_{xy} R_{yy}^{-1/2} = F K G^T \quad \text{and} \quad F^T G = K,
\]

\[
F^T F = I, \quad G^T G = I, \quad K = \text{diag}[k_1, k_2, \ldots, k_m] \]

The diagonal matrix \( K \) is the canonical correlation
matrix of canonical correlations \( k_r \). The canonical
correlations are arranged in descending order \( (1 \geq k_1 \geq \ldots \geq k_m > 0) \).

The canonical coordinates of \( \mathbf{x} \) and \( \mathbf{y} \) are defined as

\[
\begin{bmatrix} \mathbf{u} \\ \mathbf{v} \end{bmatrix} = \begin{bmatrix} F^T & 0 \\ 0 & G^T \end{bmatrix} \begin{bmatrix} R_{xx}^{1/2} & 0 \\ 0 & R_{yy}^{1/2} \end{bmatrix} \begin{bmatrix} \mathbf{x} \\ \mathbf{y} \end{bmatrix} \]

Correspondingly, the matrices

\[
W^T = F^T R_{xx}^{-1/2} \quad \text{and} \quad D^T = G^T R_{yy}^{-1/2}
\]

map \( \mathbf{x} \) and \( \mathbf{y} \) to their corresponding canonical coordinates \( \mathbf{u} \)
and \( \mathbf{v} \). Thus we may rewrite the canonical coordinate map of
Eq. (4) as

\[
\begin{bmatrix} \mathbf{u} \\ \mathbf{v} \end{bmatrix} = \begin{bmatrix} W^T & 0 \\ 0 & D^T \end{bmatrix} \begin{bmatrix} \mathbf{x} \\ \mathbf{y} \end{bmatrix}
\]

The composite vector of canonical coordinates, \( [\mathbf{u}^T \mathbf{v}]^T \) has
covariance matrix

\[
E \left[ \begin{bmatrix} \mathbf{u} \\ \mathbf{v} \end{bmatrix} \begin{bmatrix} \mathbf{u}^T \\ \mathbf{v}^T \end{bmatrix} \right] = \begin{bmatrix} R_{uu} & R_{uv} \\ R_{uv} & R_{vv} \end{bmatrix}
\]

\[
= \begin{bmatrix} W^T R_{xx} W & W^T R_{xy} D \\ D^T R_{xx} W & D^T R_{yy} D \end{bmatrix} = \begin{bmatrix} I & K \\ K & I \end{bmatrix}
\]

The canonical correlation matrix \( K \) is the cross
covariance matrix of \( \mathbf{u} \) and \( \mathbf{v} \). That is

\[
E[\mathbf{u}^T \mathbf{v}] = K = W^T R_{xx} D = F^T R_{xx}^{-1/2} R_{xy} R_{yy}^{-1/2} G
\]

The squared canonical correlations \( k_r^2 \) decompose the
linear dependence \( H \) between \( \mathbf{x} \) and \( \mathbf{y} \), which is measured by
the Hadamard ratio

\[ H = \det(I - KK^T) = \prod_{i=1}^{m}(1 - k^2_i) \]  

(9)

In the case where x and y are marginally Gaussian, the squared canonical correlation decomposes the mutual information \( I(x,y) \) between x and y

\[ I(x,y) = -\frac{1}{2} \log \det(I - KK^T) = -\frac{1}{2} \sum_{i=1}^{m} \log(1 - k^2_i) \]  

(10)

The conventional method of canonical coordinate decomposition, i.e., Eq. (4), requires the computation of the SVD of the coherence matrix \( C = R_{xx}^{1/2}R_{xy}R_{yy}^{-1/2} \) and the products \( F^TR_{xx}^{1/2} \) and \( G^TR_{yy}^{-1/2} \), which involve computation of matrix square-root inverses. In addition, the conventional method does not allow for recursive extraction of a subset of canonical coordinates at a lower computational cost. These deficiencies of the conventional method motivate our next discussion.

3. A network for recursive extraction of canonical coordinates

This section presents a network structure and a set of updating rules to recursively extract the canonical coordinates of two data channels. The updating rules are derived so that no matrix inversion or square root computation is required. The network may be trained in either batch or sequential mode and thus may be used for online applications as well. Let \( w_i \in \mathbb{R}^{nx1} \) and \( d_i \in \mathbb{R}^{nx1} \) denote the \( i \)th columns of \( W \) and \( D \). Then, the \( i \)th canonical coordinates of \( x \) and \( y \) and their corresponding canonical correlation are

\[ u_i = w_i^T x, v_i = d_i^T y, \text{ and } k_i = E[u_i,v_i] = w_i^T R_{xy} d_i \]  

(11)

From here on, we refer to \( w_i \) and \( d_i \) as the \( i \)th canonical coordinate mapping vectors. From Eq. (7), we have

\[ E[u_iu_j] = w_i^T R_{xx} w_j = \delta(i-j) \]

\[ E[v_i v_j] = d_i^T R_{yy} d_j = \delta(i-j) \]

(12)

\[ E[u_i v_j] = w_i^T R_{xy} d_j = k_i \delta(i-j) \]

where \( \delta(\cdot) \) is the Kronecker delta. Noting that \( k_1 = w_1^T R_{xy} d_1 \) is the largest canonical correlation, the problem of finding the first canonical coordinate mapping vectors, \( w_1 \) and \( d_1 \), may be formulated as the maximization problem

\[ \max_{w_1,d_1} w_1^T R_{xy} d_1 \]

subject to the constraints

\[ w_1^T R_{xx} w_1 = 1 \]  

\[ d_1^T R_{yy} d_1 = 1 \]  

(13)

Using the method of Lagrange multipliers we may rewrite the constrained optimization problem defined by Eqs. (13) and (14) as minimizing the objective function \( J_1 \) of the form

\[ J_1 = -w_1^T R_{xy} d_1 + (w_1^T R_{xx} w_1 - 1) \frac{\lambda_{1,1}}{2} \]

\[ + (d_1^T R_{yy} d_1 - 1) \frac{\lambda_{1,2}}{2} \]  

(15)

where \( \lambda_{1,1} \) and \( \lambda_{1,2} \) are Lagrange multipliers that enforce the constraints in Eq. (14).

Now, assume that the first \( r < m \) columns of \( W \) and \( D \) have already been found. Let \( W_r \in \mathbb{R}^{nxr} \) and \( D_r \in \mathbb{R}^{nxr} \) be the matrices that, respectively, contain the first \( r \) columns of \( W \) and \( D \). That is

\[ W_r = [w_1, \ldots, w_r] \]  

\[ D_r = [d_1, \ldots, d_r] \]  

(16)

The first \( r \) canonical coordinates of \( x \) and \( y \) are then given by

\[ u_r = [u_1, \ldots, u_r]^T = W_r^T x \]  

\[ v_r = [v_1, \ldots, v_r]^T = D_r^T y \]  

(17)

By deflating the contribution of the first \( r \) canonical coordinates \( u_r \) and \( v_r \) from the input channels, we may formulate the problem of finding the \( (r+1) \)th pair of canonical coordinates as one of finding the first canonical coordinate pair of the deflated input channels. This may be done by replacing \( R_{xy} \) in Eq. (15) with its deflated version \( (I - R_{xx} W_r^T R_{xy} (I - R_{yy} D_r D_r^T)^{-1}) \) (See Appendix for the proof). Thus, the \( (r+1) \)th pair of canonical coordinate mapping vectors \( w_{r+1} \) and \( d_{r+1} \) may be found by minimizing the objective function

\[ J_{r+1} = -w_{r+1}^T (I - R_{xx} W_r^T R_{xy} (I - R_{yy} D_r D_r^T)^{-1}) d_{r+1} \]

\[ + (w_{r+1}^T R_{xx} w_{r+1} - 1) \frac{\lambda_{r+1,1}}{2} \]

\[ + (d_{r+1}^T R_{yy} d_{r+1} - 1) \frac{\lambda_{r+1,2}}{2} \]  

(18)

where \( \lambda_{r+1,1} \) and \( \lambda_{r+1,2} \) are Lagrange multipliers that guarantee the unit variance property of the new pair of coordinates,

\[ E[u_{r+1}^2] = w_{r+1}^T R_{xx} w_{r+1} = 1 \]

(19)

\[ E[v_{r+1}^2] = d_{r+1}^T R_{yy} d_{r+1} = 1 \]

Taking the partial derivatives of \( J_{r+1} \) with respect to \( w_{r+1} \) and \( d_{r+1} \) yields

\[ \frac{\partial J_{r+1}}{\partial w_{r+1}} = -(I - R_{xx} W_r^T R_{xy} (I - R_{yy} D_r D_r^T)^{-1}) \]

\[ + R_{xx} w_{r+1} \lambda_{r+1,1} \]  

(20)

\[ \frac{\partial J_{r+1}}{\partial d_{r+1}} = -(I - R_{xx} W_r^T R_{xy} (I - R_{yy} D_r D_r^T)^{-1}) \]

\[ + R_{yy} d_{r+1} \lambda_{r+1,2} \]
At the solution the constraints in Eq. (19) are satisfied. Moreover, $w_{r+1}$ and $d_{r+1}$ are, respectively, orthogonal to $R_{xx}W_r$ and $R_{yy}D_r$. That is

$$w_{r+1}^T R_{xx} W_r = 0 \quad \text{and} \quad d_{r+1}^T R_{yy} D_r = 0 \quad (21)$$

Using Eqs. (19) and (21) the optimal values of Lagrange multipliers in Eq. (18) are found to be

$$\lambda_{r+1,1} = \lambda_{r+1,2} = \lambda_{r+1} = w_{r+1}^T R_{xx} d_{r+1} = k_{r+1} \quad (22)$$

From Eq. (6) the $(r + 1)$th canonical coordinate pair of $x$ and $y$ is given by

$$u_{r+1} = w_{r+1}^T x \quad \text{and} \quad v_{r+1} = d_{r+1}^T y \quad (23)$$

Using Eqs. (17) and (21) we may rewrite Eq. (23) as

$$u_{r+1} = w_{r+1}^T (I - R_{xx} W_r W_r^T ) x - d_{r+1}^T u_r \quad \text{and} \quad v_{r+1} = d_{r+1}^T (I - R_{yy} D_r D_r^T ) y - p_r^T v_r \quad (24)$$

where

$$q_r^T = w_{r+1}^T R_{xx} W_r \quad \text{and} \quad p_r^T = d_{r+1}^T R_{yy} D_r \quad (25)$$

The pair of equations in Eq. (24) may be used to define a network structure for extracting the $(r + 1)$th pair of canonical coordinates, given the first $r$ pairs. Each equation in Eq. (24) defines a single layer subnetwork that features a feedback set of weights from the input to the output and a set of lateral connections that connect the first $r$ nodes to the $(r + 1)$th node. Fig. 1 shows the structure of this network. In this structure, $W_r$ and $D_r$ are the weight matrices that map $x$ and $y$ to their first $r$ canonical coordinates $u_r$ and $v_r$. Given these weights, the network may be trained, by minimizing $J_{r+1}$ in Eq. (18), to extract the $(r + 1)$th canonical coordinate pair and the corresponding mapping vectors. The weight vectors $w_{r+1}$ and $d_{r+1}$ are trained to maximize the correlation between the outputs $u_{r+1}$ and $v_{r+1}$ and make them unity variance. The lateral weight vector $q_r$ is trained to orthogonalize $u_r$ (the first $r$ canonical coordinates of $x$) to $u_{r+1}$ (the $(r + 1)$th canonical coordinate of $x$). Similarly, the lateral weight vector $p_r$ is trained to orthogonalize $v_r$ to $v_{r+1}$. The lateral connections perform a deflation process that subtracts the contributions of the already extracted coordinates from the linear subspaces of $x$ and $y$. This structure allows for adding new nodes for extracting additional canonical coordinates without the need for retraining the previous nodes.

Using the stochastic gradient descent learning algorithm, with instantaneous values of covariance matrices inserted into Eq. (20), we may derive the following updating rules for $w_{r+1}$ and $d_{r+1}$

$$w_{r+1}(j + 1) = w_{r+1}(j) + [(x(j + 1) - S_r(j + 1)) u_r(j + 1) - \beta v_r(j + 1)] x(j + 1) \times (j + 1) \beta = (j + 1) \beta \quad (26)$$

$$d_{r+1}(j + 1) = d_{r+1}(j) + [(y(j + 1) - T_r(j + 1)) v_r(j + 1) - \beta u_r(j + 1) + \beta v_r(j + 1)] \times (j + 1) \beta \quad (27)$$

where $j$ is the index of iteration. Matrices $S_r$ and $T_r$ are updated to asymptotically approximate $R_{xx} W_r$ and $R_{yy} D_r$, respectively. From Eq. (22), the Lagrange multiplier $\lambda_{r+1} = \lambda_{r+1,1} = \lambda_{r+1,2}$ shall be updated to asymptotically approximate $w_{r+1}^T R_{xx} d_{r+1} = k_{r+1}$. Thus the updating rules for $S_r$, $T_r$, and $\lambda_{r+1}$ are

$$S_r(j + 1) = \frac{j}{j + 1} S_r(j) + \frac{1}{j + 1} x(j + 1) u_r^T(j + 1) \quad (28)$$

$$T_r(j + 1) = \frac{j}{j + 1} T_r(j) + \frac{1}{j + 1} y(j + 1) v_r^T(j + 1) \quad (29)$$

$$\lambda_{r+1}(j + 1) = \frac{j}{j + 1} \lambda_{r+1}(j) + \frac{1}{j + 1} w_{r+1}^T(j + 1) x(j + 1) \quad (30)$$

Finally using Eq. (25) the learning rules for the lateral weight vectors $q_r$ and $p_r$ may be written as

$$q_r(j + 1) = S_r^T(j + 1) w_{r+1}(j + 1) \quad (31)$$

$$p_r(j + 1) = T_r^T(j + 1) d_{r+1}(j + 1) \quad (32)$$

Thus we may summarize the step-by-step training algorithm for extracting the $(r + 1)$th canonical coordinate pair for $r = 0, 1, \ldots, m - 1$ and the corresponding mapping.
vectors as
\[ u_{r+1}(j) = w^T_{r+1}(j)x(j+1) \text{ and } v_{r+1}(j) = D^T_{r+1}y(j+1) \]
\[ u_{r+1}(j+1) = w^T_{r+1}(j+1)x(j+1) - q_j^T(j)u_{r+1}(j+1) \]
\[ v_{r+1}(j+1) = d^T_{r+1}(j+1)y(j+1) - p_j^T(j)v_{r+1}(j+1) \]
\[ \lambda_{r+1}(j+1) = \frac{1}{j+1}[\lambda_{r+1}(j) + w^T_{r+1}(j)x(j+1)y^T(j+1)d_{r+1}(j)] \]
\[ S_r(j+1) = \frac{1}{j+1}[S_r(j) + x(j+1)u^T_{r+1}(j+1)] \]
\[ T_r(j+1) = \frac{1}{j+1}[T_r(j) + y(j+1)v^T_{r+1}(j+1)] \]
\[ w_{r+1}(j+1) = w_{r+1}(j) + [x(j+1) - S_r(j+1)u_r(j+1)]v_r(j+1) \]
\[ -x(j+1)(j+1)^T w_{r+1}(j)\lambda_{r+1}(j+1)\beta(j+1) \]
\[ d_{r+1}(j+1) = d_{r+1}(j) + [y(j+1) - T_r(j+1)v_r(j+1)]u_r(j+1) \]
\[ -y(j+1)(j+1)^T d_{r+1}(j)\lambda_{r+1}(j+1)\beta(j+1) \]
\[ q_r(j+1) = S^T_r(j+1)w_{r+1}(j+1) \]
\[ p_r(j+1) = T^T_r(j+1)d_{r+1}(j+1) \]
(29)

The initial values \( w_{r+1}(0) \in R^{nx1} \), \( d_{r+1}(0) \in R^{nx1} \), \( q_r(0) \in R^{nx1} \), \( p_r(0) \in R^{nx1} \), \( S_r(0) \in R^{nxr} \), \( T_r(0) \in R^{nxr} \), and \( \lambda_{r1} \) may be chosen randomly. The learning rate \( \beta \) may be varied or kept fixed (Haykin, 1991). After convergence, the linear dependence captured by the first \((r + 1)\) pair of canonical coordinates is
\[ H_r = \prod_{i=1}^{r+1}(1 - \lambda_i^2) = \prod_{i=1}^{r+1}(1 - \lambda_i^2) \]  
(30)

and in case that \( x \) and \( y \) are marginally Gaussian, the mutual information preserved by the first \((r + 1)\) pair of canonical coordinates becomes
\[ I_r(x,y) = -\frac{1}{2} \sum_{i=1}^{r+1} \log(1 - \lambda_i^2) = -\frac{1}{2} \sum_{i=1}^{r+1} \log(1 - \lambda_i^2) \]  
(31)

Since in most applications, the number of canonical coordinate pairs to be extracted is not known a priori, we may run a test based on Eqs. (30) or (31) to determine if the number of linear dependence or mutual information preserved, meets a pre-specified threshold. If the threshold is not reached, we may add another node to the network to extract the next pair of canonical coordinates.

4. Simulation results

In this section, the proposed network is used to recursively extract the canonical coordinate mappings for a synthesized data set. The performance of the network is demonstrated by presenting the plots of squared error between the actual canonical coordinate mappings, computed using the direct method in Eq. (5), and the ones estimated by the network, along with the plots of squared error for canonical correlations. Let \( w_i \) and \( d_i \), respectively, denote the estimate of the \( i \)th pair of the actual canonical coordinate mappings \( w \) and \( d \). We define \( e^2_w \) and \( e^2_d \) as the squared estimation error of the \( i \)th canonical coordinate mappings \( w_i \) and \( d_i \). That is
\[ e^2_w = \|w_i - \hat{w}_i\|^2 \text{ and } e^2_d = \|d_i - \hat{d}_i\|^2 \]

Also, \( e^2_{\lambda_i} = (\lambda_i - \hat{\lambda}_i)^2 \), is defined as the squared estimation error of the \( i \)th canonical correlation \( \lambda_i \). The actual canonical correlation \( \lambda_i \) is found from the SVD in Eq. (3). From Eq. (22), it is seen that the \( i \)th canonical correlation \( \lambda_i \) is estimated by the Lagrange multiplier \( \lambda_i \). The data set is formed from 500 samples of two data channels \( x \in R^{2x1} \), \( y \in R^{2x1} \) governed by the linear model
\[ x = H_1 \eta_1 \text{ and } y = H_2 \eta_2 + H_3 x \]
The matrices \( H_1 \in R^{nx4} \), \( H_2 \in R^{nx5} \) and \( H_3 \in R^{nx4} \) are used to synthesize \( x \) and \( y \) from \( \eta_1 \in R^{4x1} \) and \( \eta_2 \in R^{5x1} \), which are two independent white Gaussian vectors. The network is trained for 2500 epochs using the training algorithm in Eq. (29), without knowledge of the generating mechanism for \( x \) and \( y \). The learning rate is varied linearly from \( \beta = 5 \times 10^{-3} \) to \( 5 \times 10^{-6} \) in 2500 steps. All the initial values in Eq. (29) are randomly selected. Fig. 2(a)–(d) show the squared estimation errors \( e^2_{\lambda_i}, i \in [1,4] \) vs. the epoch index for 10 independent initializations of the network. It is seen that in all the cases the squared error approaches zero within a misadjustment error (Haykin, 1996) and thus the weights of the upper subnetwork (Fig. 1) converge to the actual canonical coordinate mapping vectors that map the first data channel \( x \) into its canonical coordinates \( u \).

The plots of the squared estimation errors \( e^2_{\lambda_i}, i \in [1,4] \) vs. epoch index for the 10 initializations are shown in Fig. 3. The convergence behaviors are very similar to those in Fig. 2. In all the cases the squared error approaches zero within a misadjustment error and thus the weights of the lower subnetwork (Fig. 1) converge to the actual canonical coordinate mapping vectors that map the second data channel \( y \) into its canonical coordinates \( v \).

Fig. 4 shows the squared estimation errors \( e^2_{\lambda_i}, i \in [1,4] \) vs. the epoch index for the 10 initializations. The plots show that the squared error decays to zero in all the cases. The estimate of the \( i \)th canonical correlation \( \lambda_i \) is given by the Lagrange multiplier \( \lambda_i \). These plots indicate that \( \lambda_i \)'s converge to the actual canonical correlations \( \lambda_i \)'s.
Fig. 2. The squared error for $\mathbf{w}_i$'s, $i \in \{1, 4\}$ vs. the epoch index for 10 independent initializations of the network (a) $i = 1$; $e_2^w = ||\mathbf{w}_1 - \bar{\mathbf{w}}_1||^2$. (b) $i = 2$; $e_2^w = ||\mathbf{w}_2 - \bar{\mathbf{w}}_2||^2$. (c) $i = 3$; $e_2^w = ||\mathbf{w}_3 - \bar{\mathbf{w}}_3||^2$. (d) $i = 4$; $e_2^w = ||\mathbf{w}_4 - \bar{\mathbf{w}}_4||^2$. In all the cases the squared error approaches zero and the weights of the upper subnetwork (Fig. 1) converge to the actual canonical coordinate mapping vectors that map the first data channel $\mathbf{x}$ into its canonical coordinates $\mathbf{u}$.

Fig. 3. The squared error for $\mathbf{d}_i$'s, $i \in \{1, 4\}$ vs. the epoch index for 10 independent initializations of the network (a) $i = 1$; $e_2^d = ||\mathbf{d}_1 - \bar{\mathbf{d}}_1||^2$. (b) $i = 2$; $e_2^d = ||\mathbf{d}_2 - \bar{\mathbf{d}}_2||^2$. (c) $i = 3$; $e_2^d = ||\mathbf{d}_3 - \bar{\mathbf{d}}_3||^2$. (d) $i = 4$; $e_2^d = ||\mathbf{d}_4 - \bar{\mathbf{d}}_4||^2$. In all the cases the squared error approaches zero and the weights of the lower subnetwork (Fig. 1) converge to the actual canonical coordinate mapping vectors that map the second data channel $\mathbf{y}$ into its canonical coordinates $\mathbf{v}$.
5. Conclusion

A new network for recursive extraction of canonical coordinates of two data channels is introduced. The network is based on a constrained minimization problem that exploits a deflation process. The deflation process is performed by incorporating lateral connections into the subnetworks. The learning rules are derived using a stochastic gradient descent algorithm. The structure of the network along with the learning rules allow for adding a new node to the network in order to extract a new canonical coordinate pair without the need to retrain the previous nodes. Unlike conventional methods, no matrix inversion, matrix square root computation, or direct SVD is required during the training. A simulation example demonstrates the validity of the proposed network and learning rules. The results confirm that the extracted canonical coordinate mappings indeed approximate the true ones.

Appendix A

Here we show that the constrained minimization problem in Eq. (18) indeed formulates the problem of finding the \((r + 1)\)th pair of canonical coordinate mappings \(w_{r+1}\) and \(d_{r+1}\). The assumption is that the matrices \(W_r\) and \(D_r\); which contain the first \(r\) columns of \(W\) and \(D\) (the first \(r\) pair of canonical coordinate mappings), have already been found.

Let us start by partitioning \(F\), \(G\) and \(K\) into

\[
F = \begin{bmatrix} F_r & F_i \end{bmatrix}, \quad G = \begin{bmatrix} G_r & G_i \end{bmatrix}, \quad K = \begin{bmatrix} K_r & 0 \\ 0 & K_i \end{bmatrix}
\]

(32)

where matrices \(F_r\) and \(G_r\) contain the first \(r\) and matrices \(F_i\) and \(G_i\) the last \(m - r\) columns of \(F\) and \(G\). The diagonal matrices \(K_r = \text{diag}[k_1, \ldots, k_r]\) and \(K_i = \text{diag}[k_{r+1}, \ldots, k_m]\) respectively, contain the first \(r\) and last \(m - r\) canonical correlations. Then from Eq. (3), we have

\[
C = R_{xx}^{-1/2} R_{xy} R_{yy}^{-1/2} = F K_r G_i^T + F_i K_i G_i^T
\]

and

\[
\begin{bmatrix} F_r^T F_r & F_i^T F_i \\ F_r^T F_i & F_i^T F_i \end{bmatrix} = \begin{bmatrix} I_r & 0 \\ 0 & I_i \end{bmatrix}
\]

(34)

\[
\begin{bmatrix} G_i^T G_r & G_i^T G_i \\ G_i^T G_i & G_i^T G_i \end{bmatrix} = \begin{bmatrix} I_r & 0 \\ 0 & I_i \end{bmatrix}
\]
where \( I_r \) and \( I_p \) are the \( r \times r \) and \( (m - r) \times (m - r) \) identity matrices. The SVD in Eq. (33), may be rewritten as

\[
R_{xy} = R_{xx}^{1/2} F_r K_r G_r^T R_{yy}^{1/2} + R_{xx}^{1/2} F_r K_r G_r^T R_{yy}^{1/2}
\]

(35)

Using Eqs. (33) and (34), it may easily be verified that the first term on the right hand side of Eq. (35) has three equivalent representations. That is

\[
R_{xx}^{1/2} F_r K_r G_r^T R_{yy}^{1/2} = R_{xx}^{1/2} F_r R_{xx}^{-1/2} R_{xx}^{1/2} G_r^T R_{yy}^{1/2}
\]

= \( R_{xx}^{1/2} F_r R_{xx}^{-1/2} R_{xx}^{1/2} G_r^T R_{yy}^{1/2} \)

(36)

Using this property, we may rewrite Eq. (35) as

\[
(I - R_{xx}^{1/2} F_r F_r^T R_{xx}^{-1/2}) R_{xy} (I - R_{yy}^{1/2} G_r G_r^T R_{yy}^{-1/2})^T
\]

= \( R_{xx}^{1/2} F_r K_r G_r^T R_{yy}^{1/2} \)

(37)

We now partition \( W \) and \( D \) into \( W = [W_r, W_p] \) and \( D = [D_r, D_p] \), where the matrices \( W_r = [w_{r+1}, \ldots, w_m] \) and \( D_r = [d_{r+1}, \ldots, d_m] \) contain the last \( m - r \) columns of \( W \) and \( D \). Then, from Eq. (5) we have

\[
F_r = R_{xx}^{1/2} W_r, \quad F_f = R_{xx}^{1/2} W_f,
\]

\[
G_r = R_{yy}^{1/2} D_r, \quad G_f = R_{yy}^{1/2} D_f
\]

(38)

Using Eq. (38), we may rewrite Eq. (37) as

\[
(I - R_{xx} W_r W_r^T) R_{xy} (I - R_{yy} D_r D_r^T)^T = R_{xx} W_r K_r D_r^T R_{yy}
\]

(39)

Pre-multiplying Eq. (39) by \( w_{r+1}^T \), post-multiplying it by \( d_{r+1} \), and noting that \( w_{r+1}^T R_{xx} W_r = [1, 0, \ldots, 0] \) and \( d_{r+1} R_{yy} D_r = [1, 0, \ldots, 0] \) results in

\[
w_{r+1}^T (I - R_{xx} W_r W_r^T) R_{xy} (I - R_{yy} D_r D_r^T)^T d_{r+1} = k_{r+1}
\]

(40)

Considering that \( k_{r+1} \) is the largest diagonal element of \( K_r \), we may formulate the problem of finding \( w_{r+1}, d_{r+1} \) as

\[
\max_{w_{r+1}, d_{r+1}} w_{r+1}^T (I - R_{xx} W_r W_r^T) R_{xy} (I - R_{yy} D_r D_r^T)^T d_{r+1}
\]

subject to the constraints

\[
w_{r+1}^T R_{xx} w_{r+1} = 1 \text{ and } d_{r+1}^T R_{yy} d_{r+1} = 1.
\]
