## Problem Statement:

Marcos Palu (pers. Comm.) reported that after the collapse of Fundao Dam in Brazil, the sediment concentration in the Doce River reached a value of $580 \mathrm{~g} / \mathrm{l}$ for about 6 hours. Consider the following river characteristics: river width 130 m , flow depth 3.5 m , flow velocity $1.1 \mathrm{~m} / \mathrm{s}$, bed slope 0.0005 , and shear velocity $0.13 \mathrm{~m} / \mathrm{s}$. Use Eq. 13.8 with the following dispersion coefficient $\mathrm{Kd}=150 \mathrm{~m} 2 / \mathrm{s}$ and the sediment settling rate $\mathrm{k}=0.0000036 \mathrm{~s}-1$ to estimate the sediment concentration as a function of time at Oculos station located 94 km downstream. Compare the results with $\mathrm{k}=0$.

Analysis:
Sediment Concentration was calculated using Equation 13.8, seen below:

$$
\left.C(x, t)=\frac{C_{0}}{2}\left\{\begin{array}{l}
e^{\frac{U x(1-\Gamma)}{2 K}}\left[\operatorname{erfc}\left(\frac{x-U t \Gamma}{2 \sqrt{K t}}\right)-\operatorname{erfc}\left(\frac{x-U(t-T) \Gamma}{2 \sqrt{K(t-T)}}\right)\right]
\end{array}\right\}, \begin{array}{l}
\left.+\frac{U x(1+\Gamma)}{2 K}\left[\operatorname{erfc}\left(\frac{x+U t \Gamma}{2 \sqrt{K t}}\right)-\operatorname{erfc}\left(\frac{x+U(t-T) \Gamma}{2 \sqrt{K(t-T)}}\right)\right]\right) \tag{13.8}
\end{array}\right\}
$$

Where parameters are as follows:

| Parameter | Variable | Value |
| :--- | :--- | :--- |
| $\mathrm{C}_{0}$ | Initial Concentration | $580 \mathrm{~g} / \mathrm{L}$ |
| $U$ | Flow Velocity | $1.1 \mathrm{~m} / \mathrm{s}$ |
| x | Station Downstream | Varied |
| t | Time | Varied |
| K | Dispersion Coefficient | $150 \mathrm{~m}^{2} / \mathrm{s}$ |
| T | Duration of Spill | 21,600 seconds |

Gamma was defined using the following equation:

$$
\Gamma=\sqrt{1+4 k K / U^{2}}
$$

Where k was either 0.0000036 per second's or 0 , for cases a and b respectively. Gamma for case a was 1.000089 and gamma for case b was 1 .

Concentration was calculated at stations $23.5,47,70.5$ and 94 at each minute. The concentrations were then plotted against time in the figure below:

## Sediment Concentration after Dam Breach

When overlayed against Figure P.13.10, the following figure was acquired:

Case a, represented by the solid lines, fits the observed data well at station 94 . Case b, where no sediment settles out in transport, dramatically overestimates the concentration, with the peak hardly decreasing at all from the initial value. A table of Sediment Concentration and time for station 94 can be found attached.

Time

| Station | (hr) |  | $\mathrm{Cag} / \mathrm{L}$ |
| ---: | ---: | ---: | ---: |
| 94000 | $\mathrm{C} \mathrm{b} \mathrm{g} / \mathrm{L}$ |  |  |
| 94000 | 0 |  |  |
| 94000 | 1 |  |  |
| 94000 | 2 |  |  |
